

[tex23] Thermodynamics of black-body radiation

Electromagnetic radiation inside a cavity is in thermal equilibrium with the walls at temperature T . The radiation has an energy density that depends only on the temperature, i.e. its internal energy has the form $U(T, V) = Ve(T)$. The radiation pressure is determined by the energy density alone: $p = \frac{1}{3}e(T)$. (a) Use the consistency equations for the total differential dS to show that the energy density has the form $e(T) = \sigma T^4$, where σ is a constant, now known as the *Stefan-Boltzmann constant*. In this argument, the additional assumption enters that $e(T) \rightarrow 0$ for $T \rightarrow 0$. (b) Determine the entropy $S(T, V)$ and the thermodynamic potentials $U(S, V)$, $E(S, p)$, $A(T, V)$, $G(T, p)$. (c) Determine the isotherms and adiabats in the (V, p) -plane. (d) Determine the response functions $C_V, C_p, \kappa_T, \kappa_S, \alpha_p$.

Solution:
